Adopted Regulation Strategy Lake of the Woods Control Board November 6, 2025

The Lake of the Woods Control Board held a Regulation Meeting in Kenora and via teleconference on October 30, 2025, when it adopted a Regulation Strategy to guide operations through the beginning of March 2026. The strategy was formulated considering basin conditions, hydrological and meteorological forecasts, and the input of the various interests concerned with basin management. Input was provided in written and verbal reports as well as from the Board's Regulation Guide: (https://www.lwcb.ca/reg-guide/index.html).

For an update on current conditions, please refer to the Basin Data section of the Board's web site at https://www.lwcb.ca/waterflowdata.html. For regulation actions and directives taken under the strategy please see the Regulation Actions at http://www.lwcb.ca/regulation/index.html.

At the time of the Regulation Meeting, flows and levels were in the low to low-normal range across the entire Winnipeg River Basin. Summer precipitation patterns varied across the basin. In the South of the basin, conditions were mainly dry with periods of relief from intense precipitation in July and at the end of September. This rainfall increased inflows to the lake, helping to avoid severe drought conditions and maintaining a stable level on Lake of the Woods, slightly below the normal range. Inflow to Lake of the Woods returned to the normal range in October with increased precipitation, which brought the lake level into the normal range by the end of October. In contrast, the North part of the basin received much less rainfall from July to September. The year-to-date precipitation for Lake St. Joseph, Lac Seul and the English River sub-basins was below 5th percentile by October 15th. Reflecting the dry conditions, inflow to Lac Seul remained between 5th and 25th percentile for the period of July through October.

Outflows of Lake of the Woods and Lac Seul were manged to match inflow, mirroring the dry conditions, and ensuring lake levels did not fall over the summer. When possible, outflow increases were made to balance flows downstream. After a dry September, frequent precipitation in October ensured the storage gained on both lakes in preparation for winter drawdown was maintained. By the end of October, the level of Lake of the Woods was at 30th percentile while the level of Lac Seul reached 45th percentile.

The strategy is focused on two periods including regulation until freeze-up (typically mid to end of November) and the winter period until early March. The strategy specifies key aims and how the Board intends to balance these under a range of possible flow conditions should they develop during the strategy period. The goal of balancing conditions across the entire basin is a complex task given the diverse nature of the different, and sometimes conflicting, interests and the largely unpredictable nature of the hydrology that drives the system.

Lac Seul

A) Seasonal Considerations

Inflows to Lac Seul were mainly in the low range from June to October as was the lake outflow. Despite the dry conditions a slightly higher end-of-October level target recommended under low inflow conditions for Lac Seul was achieved leaving the lake well positioned before the start of drawdown.

Ideal or desirable regulation objectives for the next several months, based on input provided to the Board, include the following:

<u>Up to and During Freeze-up (mid-November)</u>

- Until freeze-up, gradually adjust outflows to those desirable for winter outflow and end-of-winter drawdown targets.
- Regulate Lac Seul outflow to assist in providing satisfactory freeze-up conditions on the English and Winnipeg Rivers as well as on Lac Seul.
- Outfitters on Lac Seul prefer a maximum freeze-up level of 356.31 m (1169 ft).
- Manitoba Hydro prefers that flows at Slave Falls not exceed 1400 m³/s during the ice formation period to avoid frazil ice development and related issues.

Hydropower Flows

- Operate Lac Seul primarily as a hydropower reservoir to meet winter operation requirements of downstream hydropower plants and provide core winter power demands in Ontario and Manitoba, but with consideration of other interests.
- Ontario Power Generation's minimum flows required for plant heating during the winter are:
 - a) 292 m3/s at Ear Falls GS.
 - b) 200 m3/s at Manitou Falls GS for cold temperatures and 300 m3/s for extremely cold temperatures
 - c) 200 m3/s at Caribou Falls GS.
- Manitoba Hydro's minimum flows required for hydropower production and plant heating are 170 m³/s until mid-November, 340 m³/s from mid to end of November and mid-February to mid-March, as well as 625 m³/s during the core winter period from December to mid-February at Slave Falls.
- Manitoba Hydro's preferred flow for the core-winter months from mid-November to end of March is between 675 and 960 m³/s at Slave Falls.

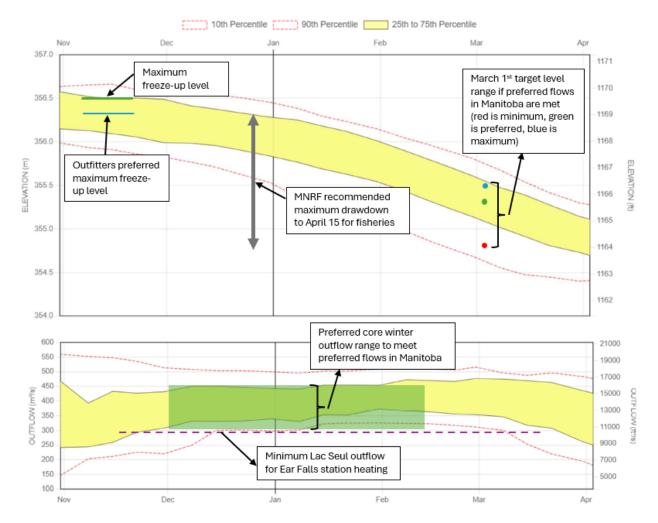

Winter Considerations

- MNRF recommends limiting winter drawdown on Lac Seul to:
 - a) No more than 1.5 m to protect eggs of fall spawning fish (i.e. to minimize whitefish egg exposure and mortality).
 - b) Provide adequate spring spawning conditions in shoals that are sensitive to varying water levels.
- Use Lac Seul storage to offset Lake of the Woods high/low outflow for the benefit of users of the Winnipeg River in Manitoba.

- Whiteshell Cottagers Association prefers winter levels at Nutimik Lake, no higher than 275.23 m (903 ft) to avoid ice damage. High flows can also lead to ice jams and cause localized flooding.
- Avoid closing the Lake St. Joseph diversion with resulting spill down the Albany River.
- The end-of-winter (April 15) target level for Lac Seul should be evaluated in March at the LWCB Regulation meeting to account for conditions and forecasts at that time.

A graphical representation of the winter considerations is included in the figure below.

Lac Seul Winter Considerations

B) Adopted Strategy

Regulation of Lac Seul will focus on maintaining storage until freeze up to provide sufficient flow for the core winter period, given the persistent dry conditions in the English River basin. The Board has managed outflows to position the lake level within the higher end-of-October target range, between 356.1 and 356.3 m (1168.3 and 1169.0 ft), and this will allow outflow to be increased to the normal range over the winter. However, with inflow falling to 10th percentile over the last few months and annual inflow sitting at the 5th lowest in the last 30 years, baseflows and antecedent conditions will be considered when drawing the lake down over the winter and assessing potential water supply for refill in the spring.

Low Inflow Conditions

- Until freeze-up, maintain outflow no lower than 150 m³/s.
- Winter outflow should be no lower than 150 m³/s, with a core winter (December to mid-February) flow no lower than 250 m³/s.
- Combined with Lake of the Woods regulation, if winter core period flows are at the minimum 625 m³/s on the Winnipeg River in Manitoba, the Lac Seul March 1st elevation should preferably be no lower than 354.6 m (1163.4 ft). This objective takes into consideration low outflow from Lake of the Woods.
- Combined with Lake of the Woods regulation, if winter core period flows are at the preferred 675 m³/s on the Winnipeg River in Manitoba, the Lac Seul March 1st elevation should not be allowed to decline lower than 354.8 m (1164.0 ft). This objective takes into consideration low outflow from Lake of the Woods.

Moderate Inflow Conditions

- Until freeze-up, combined with Lake of the Woods regulation, maintain minimum Winnipeg River flows above 170 m³/s until mid-November and then above 340 m³/s until end of November at Slave Falls.
- The Lac Seul freeze-up level should preferably be no higher than 356.5 m (1169.6 ft) with outflow no higher than 425 m³/s and Winnipeg River flows in Manitoba below 1400 m³/s.
- Winter outflow should be between 200 and 450 m³/s with a core winter flow between 300 and 400 m³/s.
- Lac Seul should be drawn down over the winter to meet hydropower requirements by supplying a core winter flow on the Winnipeg River between 675 and 960 m³/s at Slave Falls.
- Given the dry basin conditions heading into November, target a March 1st level based on snowpack development as follows:
 - a) If moderate snowpack develops, target a level preferably no higher than 355.15 m (1165.2 ft) and limited to a maximum of 355.5 m (1166.3 ft) to address the risk of higher spring flows.
 - b) If snowpack is below normal and if additional storage is required, target a level no higher than 355.6 m (1166.7 ft), and preferably no higher than 355.5 m (1166.3 ft), subject to flood risk constraints.

• Regluate the level of Lac Seul so that the level on March 1st is no lower than 354.87 m (1164.4 ft).

High Inflow Conditions

- If inflow rises before freeze-up, increase outflow as appropriate to provide a reasonable balance between increased outflow and higher lake level, with due consideration of impacts on the English and Winnipeg Rivers given current low flows and levels.
- Regulate Lac Seul outflow to as high as 500 m³/s to prevent the lake exceeding a March 1st level of 355.6 m (1166.7 ft).
- Communicate with First Nation communities on Lac Seul and the English River, and with Grand Council Treaty #3 to keep communities informed of the potential for flooding and to assist in the determination of an appropriate balance of upstream and downstream interests.
- If 500 m³/s is insufficient outflow to stay below 355.6 m (1166.7 ft), aim to limit or close the diversion into Lac Seul whether or not the Lake St. Joseph diversion is under LWCB authority. (Note: The Board only has authority to restrict diversion flow when Lac Seul exceeds 356.62 m in November and December, and 356.31 m from January to March. However, Manitoba can restrict diversion flow when Winnipeg River flows in Manitoba exceed 963 m³/s and Ontario Power Generation (OPG) can also be requested to restrict diversion flow voluntarily.)
- Once the diversion is closed, increase outflow to the extent necessary to ensure that the March 1st lake level is no higher than 355.8 m (167.3 ft).
- Combined with Lake of the Woods regulation, strive to keep Winnipeg River flows in Manitoba at Slave Falls below 1600 m³/s through the winter.

Lake of the Woods

A) Seasonal Considerations

General regulation objectives for the next several months, based on input provided to the Board, include the following:

Up to and During Freeze-up (mid-November)

- Balance freeze-up levels with winter drawdown on Lake of the Woods to reduce potential infrastructure damage from ice. LOWDSA prefers a level no higher than 322.78 m (1059 ft) at freeze-up to avoid ice forming any higher than this.
- Regulate Lake of the Woods outflow to assist in providing satisfactory freeze-up conditions on the Winnipeg River. Before an insulating layer of ice and snow forms on the river, a minimum flow of 250 m³/s is preferred to avoid freezing of domestic water lines.
- Manitoba Hydro prefers that flows at Slave Falls not exceed 1400 m³/s during the ice formation period to avoid frazil ice development and related issues.
- Aim to adjust Lake of the Woods outflow to set a stable core winter flow on the Winnipeg River by freeze-up and to avoid large shifts in river level that could affect ice cover and shorelines.

Hydropower Flows

- The preferred winter flow for FirstLight, to maximize their hydropower production, is 400 to 475 m³/s at the Lake of the Woods outlet. OPG would prefer flows closer to 550 m³/s at Whitedog Falls.
- Minimum flows required for plant heating during the winter are:
 - a) 150 m³/s at the Norman Dam and Kenora Powerhouse.
 - b) For Whitedog GS, 0 m³/s for temperatures -15°C and above, 180 m³/s for temperatures lower than -15°C.
- Within the regulation parameters for Lake of the Woods, regulate outflow to assist in meeting targets/preferences for the Winnipeg River in Manitoba.
- Manitoba Hydro's minimum flows required for hydropower production and plant heating are 170 m³/s until mid-November, 340 m³/s from mid to end of November and mid-February to mid-March, as well as 625 m³/s during the core winter period from December to mid-February at Slave Falls.
- Manitoba Hydro's preferred flow for the core-winter months from mid-November to end of March is between 675 and 960 m³/s at Slave Falls.

Winter Considerations

- Adjust lake level and outflow to achieve a balance between upstream and downstream interests, as inflow dictates. Plan winter drawdown to provide the appropriate balance between the various interests.
- Limit winter drawdown to the extent possible to reduce potential damage from ice. LOWDSA prefers a that drawdown be limited to 30 to 40 cm (12 to 16 in) to avoid infrastructure damage.
- MNRF recommends limiting winter drawdown on Lake of the Woods to:
 - a) No more than 30 cm (12 in) to protect the eggs of fall spawning fish.
 - b) An end-of-winter level no lower than 322.50 m (1058 ft) to provide adequate spring spawning conditions.
- MNRF recommends a Lake of the Woods minimum level of 322.20 m (1057.1 ft) while the lake is ice covered.
- MNRF recommends limiting winter drawdown on the Winnipeg River to no more than 1.0 m (3.0 ft).

A graphical representation of the winter considerations is included in the figure below.

10th Percentile 90th Percentile 25th to 75th Percentile Dec 323.2 323.1 LOWDSA preferred maximum freeze-up level 323.0 End-of-winter target level 322.9 range (green is preferred, blue is fisheries minimum) ELEVATION (m) 322.8 Freeze-up target level 322.7 range Preferred maximum 322.6 drawdown for fisheries and LOWDSA 322.5 1058 322.4 322.3 Preferred core winter outflow range to meet preferred flows in Manitoba 25000 700 23000 600 21000 19000 OUTFLOW (m) 500 17000 Minimum flow for 15000 400 domestic water lines 13000 11000 300 Minimum outflow for Norman 9000 and Kenora station heating 200 7000 5000 100 Dec Feb Mar

Lake of the Woods Winter Considerations

B) Adopted Strategy

Regulation of Lake of the Woods will also focus on maintaining storage until freeze up. Annual inflow was ranked 5th lowest over the last 30 years and although lake levels were below normal over the summer, outflows were managed to achieve a level of 322.7 m (1058.7 ft) heading into the winter. Regulation over the winter will take into consideration preferences of all interest groups, and outflow and drawdown will be adjusted as the winter progresses and conditions change.

Low Inflow Conditions

- If dry conditions persist until freeze-up, conserve water to the extent possible, while balancing upstream and downstream interests.
- Winter outflow should be no lower than 150 m³/s and preferably no lower than 200 m³/s to assist with winter heating of hydropower stations.

- If outflow is greater than 150 m³/s, the end-of-winter elevation should be no lower than 322.34 m (1057.5 ft).
- Combined with Lac Seul regulation, aim to achieve core winter flows on the Winnipeg River in Manitoba no lower than 625 m³/s to meet minimum winter peak period power demands. Preferentially increase Lac Seul outflow first and try to maintain an end-of-winter level on Lake of the Woods no lower than 322.34 m (1057.5 ft) in case of continued drought conditions in the spring.
- If inflow allows, and combined with Lac Seul regulation, increase outflows to achieve a flow of 675 m³/s at Slave Falls with an end-of-winter level no lower than 322.38 m (1057.7 ft).

Moderate Inflow Conditions

- Target for a Lake of the Woods level at freeze-up between 322.55 and 322.8 m (1058.2 to 1059.1 ft), with outflow preferably between 150 and 450 m³/s. If high or low inflow prevents reaching targets, aim to be as close as feasible.
- Combined with Lac Seul regulation, adjust Lake of the Woods outflow to meet Winnipeg River minimum flow at Slave Falls in Manitoba of 170 m³/s up to November 15, and 340 m³/s from November 16 to 30, and below 1400 m³/s during the ice formation period.
- Adjust winter outflow to be between 300 and 700 m³/s and avoid large reductions in outflow that would cause levels on the Winnipeg River to drop more than 1.0 m (3.0 ft).
- Target for a preferred end-of-winter level of 322.38 m (1057.7 ft), but not above 322.5 m (1058.0 ft), which aligns with the preferred maximum drawdown of 30 cm (12 in) if freeze-up levels are within the proposed target range.
- Combined with Lac Seul regulation, target winter core period flows between 675 and 960 m³/s on the Winnipeg River at Slave Falls in Manitoba.

High Inflow Conditions

- Adjust outflow as necessary to target an end-of-winter level no higher than 322.60 m (1058.4 ft) while considering the impact of increased outflow downstream, both in Ontario and Manitoba, in balance with higher water levels on the lake.
- If winter conditions indicate above normal risk of high spring inflow, aim for end-of-winter level no higher than 322.40 m (1057.7 ft) with outflow no higher than 700 to 800 m³/s,
- Communicate with First Nation communities on Lake of the Woods and the Winnipeg River, and with Grand Council Treaty #3 to keep communities informed of the potential for flooding and to assist in the determination of an appropriate balance of upstream and downstream interests.
- Combined with Lac Seul regulation, strive to keep Winnipeg River flows in Manitoba below 1600 m³/s through the winter.
